

Roberto Speaker Script (2-3 minutes)

Opening (before Slide 1)

Good day everyone. We built **Roberto** to answer one urgent climate question: how do we turn flood risk data into decisions that protect people in real time?

Key framing: Roberto is **user-centered at the front door** and **rescuer-centered in operations**. Citizens are the signal; rescuers are the response engine – Roberto connects both in one real-time workflow.

Self Intro (new intro slide)

Hi, I'm **Xy**. I am a full-stack developer at **HeyApril**, a US startup building a tax SaaS optimizer for creators. I previously worked as an AI Engineer Intern at **AIFirst** and as an AI QA Engineer at **Boost Capital**, a Singapore startup.

Slide 1 – The Problem

Every typhoon, families face rising water before help can arrive. In the Philippines, flood exposure is constant, so speed and local context matter more than generic alerts.

Slide 2 – The Gap

Today, coordination is fragmented: city-wide warnings are broad, field reports are manual, and people nearby who can help are often disconnected. The result is delayed action during the most critical minutes.

Slide 3 – Introducing Roberto

Roberto is a disaster response network for Metro Manila. It connects community reporting, operational coordination, and risk intelligence in one shared map experience.

Slide 4 – Coverage Intelligence

Before a crisis, Roberto shows where hazard is high and protection is weak by combining NOAA hazard zones, DPWH flood-control projects, and city boundaries. This gives LGUs and communities a clearer picture of where exposure remains.

Slide 5 – Incident Command

During an incident, reports move through a clear human workflow: **PING to VERIFIED to PRIORITIZED to ASSIGNED to RESOLVED**. Citizens report, coordinators decide, responders execute.

Slide 6 – Community Network

Beyond command-and-control, Roberto enables nearby people to connect and help each other. This turns bayanihan into a practical, location-aware support network.

Slide 7 – AI Guidance

For each ping, Roberto adds context-aware guidance using hazard level, weather, and location. When AI confidence is low, it safely falls back to conservative preparedness steps.

Slide 8 – Coordinator View

Coordinators get KPI visibility, incident filtering, and conflict-safe status updates with audit trails. This keeps accountability with people, not with a black-box model.

Slide 9 – Responder View

Responders receive exact coordinates, incident context, and nearby critical facilities to act faster in the field. Resolution notes close the loop and preserve what happened.

Slide 10 – Accessibility

The system is bilingual in English and Filipino so warnings and actions are understandable under stress. If people cannot understand guidance quickly, the system fails.

Slide 11 – Architecture

Roberto is built on open data and practical infrastructure: React + Mapbox on the frontend, Express + SQLite on the backend, SSE for realtime updates, and role-based access controls.

Slide 12 – Closing Answer

So how can technology help humanity live in right relationship with Earth's natural systems?

By starting with nature's signals first – where water flows, where risk concentrates, and where protection is incomplete – then translating that into local, human-led action.

Roberto does not try to "beat" the flood. It helps communities ****understand, adapt, and coordinate**** so fewer people face climate risk alone.

20-second Final Line (optional)

"Roberto is climate technology grounded in reality: open data, human accountability, and community action – so adaptation is not abstract policy, but something people can do in the next five minutes."
